Strategic Brief: Final Business Analytics Dashboard

Week 12 • Final dashboard and strategic recommendations • Based on the supplied Week 9 dataset snapshot

1. Situation

The organization’s available extracts cover three separate operating domains: real-estate listings, customer profiles, and a product catalogue. The final dashboard consolidates their key indicators into one executive view while preserving separate domain sections because no reliable shared key was supplied. The analysis is descriptive and should be used to prioritize investigation rather than to claim causation.

The snapshot contains 600 property listings, 200 customer records, and 50 products. In real estate, 209 listings are marked sold (34.83%), with a median listing price of ■172.595 lakh and average time on market of 183.7 days. Customer records contain 2,307 orders and 4,992,621 recorded revenue units; the currency is not identified. Six customers are flagged as churned (3.00%). The product catalogue contains 13,857 stock units against 5,276 average monthly sales units, with an unweighted average gross margin of 58.62%. Five products are flagged because stock is below their average monthly sales.

2. Key findings

Area	Finding	Management reading
Property	City sold rates range from 25.81% in Chennai to 43.04% in Pune. Bengaluru is 38.36%; it has the highest median city price in the supplied city table at ■221.27 lakh.	Investigate lead quality, listing mix, pricing and time-to-close before reallocating effort.
Customers	App has the highest recorded channel revenue (1,468,234 source units) and highest average revenue/customer (28,788.9). Offline has the highest channel churn rate (6.12%); Website is 0% in this snapshot.	Protect high-value App engagement and investigate Offline retention; small sample size limits certainty.
Products	Five products have stock below average monthly sales. Category gross margins range from 55.89% (Grocery) to 60.66% (Beauty).	Prioritize SKU-level replenishment review; protect margin and avoid indiscriminate stock build-up.

3. Implications

The property sold-rate spread suggests an opportunity to compare city-level conversion processes, but city differences may reflect property type, price band, inventory age, and sample composition. The 183.7-day average time on market reinforces the need to examine listing ageing and price competitiveness. Customer revenue concentration by channel can guide service and campaign testing, while the higher Offline churn rate merits a targeted diagnostic rather than a blanket channel cut. Inventory risk is immediate at SKU level: stock below average monthly sales can create potential stockouts if demand persists, although a single monthly average is not a full forecast. Gross-margin comparisons should be considered alongside sales velocity and working-capital cost.

Strategic recommendations and delivery plan

4. Prioritized recommendations

Priority 1 — Resolve stock-risk SKUs and establish replenishment controls

Within the next 1–2 weeks, obtain the original product-level file, validate the five flagged SKUs, and calculate stock cover, lead time, reorder point, and supplier constraints. Replenish only after confirming current demand and open purchase orders. Expected impact: lower exposure to avoidable stockouts and lost sales on the five flagged items; improved inventory decisions through SKU-level visibility. No numeric uplift is claimed because SKU-level quantities and lead times were not present in the retrieved source files.

Priority 2 — Run a focused Offline customer-retention diagnostic

Within 2–4 weeks, segment the Offline cohort by tenure, order frequency, recency, and customer value; review service complaints and repeat-purchase barriers. Pilot a low-cost win-back or service-recovery intervention and compare it with a holdout group. Expected impact: identify whether the 6.12% observed Offline churn rate is driven by a remediable issue and create a measurable route to retaining at-risk customers. Do not assume the observed difference is causal.

Priority 3 — Improve city conversion and listing-age management

Within 30 days, compare city sold rates using like-for-like property types and price bands; review aged listings, enquiry-to-visit conversion, price changes, and agent response time. Start with Chennai’s 25.81% sold rate and Pune’s 43.04% as contrasting diagnostic cases, not as proof of best/worst management performance. Expected impact: clearer identification of controllable conversion bottlenecks, better pricing discipline, and reduced time spent on stale listings.

5. Measurement and governance

Track a monthly scorecard: sold rate and days on market by comparable city/property cohort; churn and repeat-order rate by acquisition channel; SKU stock cover, stockout incidents, and gross margin by product. Assign an owner and baseline before each intervention, then report results against a defined comparison period or holdout. Confirm the customer revenue currency and source refresh date with the data owner before financial reporting. The peer-review log from Week 9 was explicitly marked illustrative; obtain one real peer review and record the reviewer, date, comments, and evidence before marking that activity complete.

6. Data limitations

The available project record provided aggregate city, channel, and category data but not the original raw CSVs in the retrieved file set. Therefore, the dashboard does not invent product IDs or individual stock gaps for the five risk products. Revenue remains labelled in source units; the refresh date is not supplied; and city comparisons are not adjusted for listing mix. The three domains remain separate because no common join key was documented. Recommendations are directional and their expected impact is operational, not a quantified forecast.
